Memory Management

- Subdividing memory to accommodate multiple processes
- Memory needs to be allocated to ensure a reasonable supply of ready processes to consume available processor time

- Relocation
 - Programmer does not know where the program will be placed in memory when it is executed
 - While the program is executing, it may be swapped to disk and returned to main memory at a different location (relocated)
 - Memory references must be translated in the code to actual physical memory address

Figure 7.1 Addressing Requirements for a Process

- Protection
 - Processes should not be able to reference memory locations in another process without permission
 - Impossible to check absolute addresses at compile time
 - Must be checked at run time
 - Memory protection requirement must be satisfied by the processor (hardware) rather than the operating system (software)
 - Operating system cannot anticipate all of the memory references a program will make

- Sharing
 - Allow several processes to access the same portion of memory
 - Better to allow each process access to the same copy of the program rather than have their own separate copy

- Logical Organization
 - Programs are written in modules
 - Modules can be written and compiled independently
 - Different degrees of protection given to modules (read-only, execute-only)
 - Share modules among processes

- Physical Organization
 - Memory available for a program plus its data may be insufficient
 - Overlaying allows various modules to be assigned the same region of memory
 - Programmer does not know how much space will be available

Fixed Partitioning

- Equal-size partitions
 - Any process whose size is less than or equal to the partition size can be loaded into an available partition
 - If all partitions are full, the operating system can swap a process out of a partition
 - A program may not fit in a partition. The programmer must design the program with overlays

Fixed Partitioning

- Fixed partitioning in main memory is inefficient.
 - Any program, no matter how small, occupies an entire partition.
 - What about the memory left over if the program does not fit perfectly.
 - This is called **internal fragmentation**.

Figure 7.2 Example of Fixed Partitioning of a 64-Mbyte Memory

10

Placement Algorithm with Partitions

- Equal-size partitions
 - Because all partitions are of equal size, it does not matter which partition is used
- Unequal-size partitions
 - Can assign each process to the smallest partition within which it will fit
 - Queue for each partition
 - Processes are assigned in such a way as to minimize wasted memory within a partition

(a) One process queue per partition

(b) Single queue

Figure 7.3 Memory Assignment for Fixed Partitioning

Dynamic Partitioning

- Partitions are of variable length and number
- Process is allocated exactly as much memory as required
- Eventually get holes in the memory. This is called **external fragmentation**
- Must use compaction to shift processes so they are contiguous and all free memory is in one block

Figure 7.4 The Effect of Dynamic Partitioning

Dynamic Partitioning Placement Algorithm

- Operating system must decide which free block to allocate to a process.
 - Let's look at some algorithms.
- Best-fit algorithm
 - Chooses the block that is closest in size to the request
 - Despite its name: worst performer overall
 - Since smallest block is found for process, the smallest amount of fragmentation is left
 - leaves blocks too small to reallocate
 - Memory compaction must be done more often

Dynamic Partitioning Placement Algorithm

- First-fit algorithm
 - Scans memory form the beginning and chooses the first available block that is large enough
 - Fastest
 - May have many process loaded in the front end of memory that must be searched over when trying to find a free block

Dynamic Partitioning Placement Algorithm

- Next-fit
 - Scans memory from the location of the last placement
 - More often allocate a block of memory at the end of memory where the largest block is found
 - The largest block of memory is broken up into smaller blocks
 - Compaction is required to obtain a large block at the end of memory

Figure 7.5 Example Memory Configuration Before and After Allocation of 16 Mbyte Block

Buddy System

- Entire space available is treated as a single block of 2^U
- If a request of size *s* such that $2^{U-1} < s \le 2^U$, entire block is allocated
 - Otherwise block is split into two equal buddies
 - Process continues until smallest block
 greater than or equal to *s* is generated

1 Mbyte block	1 M			
Request 100 K	A = 128 K 128 K	256 K	512 K	
Request 240 K	A = 128 K 128 K	B = 256 K	512 K	
Request 64 K	$A = 128 \text{ K} \text{ c} = 64 \text{ K} \frac{64 \text{ K}}{64 \text{ K}}$	B = 256 K	512 K	
Request 256 K	$A = 128 \text{ K} \text{ C} = 64 \text{ K} \frac{64 \text{ K}}{64 \text{ K}}$	B = 256 K	D = 256 K	256 K
Release B	$A = 128 \text{ K} \text{ c} = 64 \text{ K} \frac{64 \text{ K}}{64 \text{ K}}$	256 K	D = 256 K	256 K
Release A	128 К C = 64 К 64 К	256 K	D = 256 K	256 K
Request 75 K	E = 128 K C = 64 K 64 K	256 K	D = 256 K	256 K
Release C	E = 128 K 128 K	256 K	D = 256 K	256 K
Release E	512 K		D = 256 K	256 K
Release D	1 M

Figure 7.7 Tree Representation of Buddy System

Relocation

- When program **loaded** into memory the actual (absolute) memory locations are determined
- A process may occupy different partitions which means different absolute memory locations during execution (from swapping)
- Compaction will also cause a program to occupy a different partition which means different absolute memory locations

Addresses

- Logical
 - Reference to a memory location independent of the current assignment of data to memory
 - Translation must be made to the physical address
- Relative
 - Address expressed as a location relative to some known point
- Physical
 - The absolute address or actual location in main memory

main memory

Figure 7.8 Hardware Support for Relocation

Registers Used during Execution

- Base register
 - Starting address for the process
- Bounds register
 - Ending location of the process
- These values are set when the process is loaded or when the process is swapped in

Registers Used during Execution

- The value of the base register is added to a relative address to produce an absolute address
- The resulting address is compared with the value in the bounds register
- If the address is not within bounds, an interrupt is generated to the operating system
