Priorities

- Scheduler will always choose a process of higher priority over one of lower priority
- Have multiple ready queues to represent each level of priority
- Lower-priority may suffer starvation
 - Allow a process to change its priority based on its age or execution history

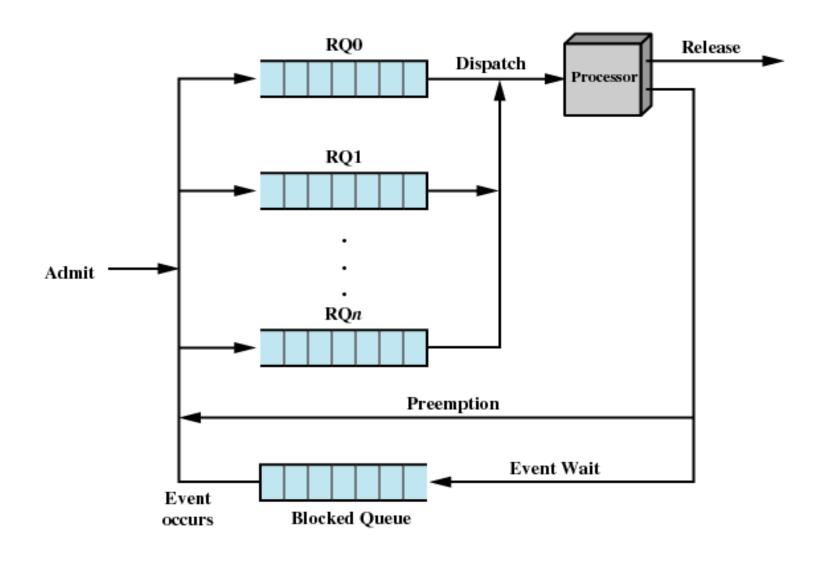

Figure 9.4 Priority Queuing

Decision Mode

Nonpreemptive

 Once a process is in the running state, it will continue until it terminates or blocks itself for I/O

Preemptive

- Currently running process may be interrupted and moved to the Ready state by the operating system
- Allows for better service since any one process cannot monopolize the processor for very long

Process Scheduling Example

Table 9.4 Process Scheduling Example

Process	Arrival Time	Service Time
A	0	3
В	2	6
С	4	4
D	6	5
Е	8	2

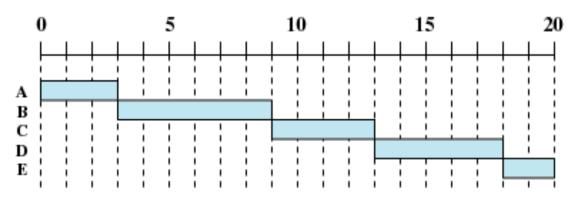

First-Come-First-Served

Table 9.4 Process Scheduling Example

	CE	'C)
(1'		S

Process	Arrival Time	Service Time
A	0	3
В	2	6
С	4	4
D	6	5
E	8	2

- Each process joins the Ready queue
- When the current process ceases to execute, the oldest process in the Ready queue is selected

First-Come-First-Served (FCFS)

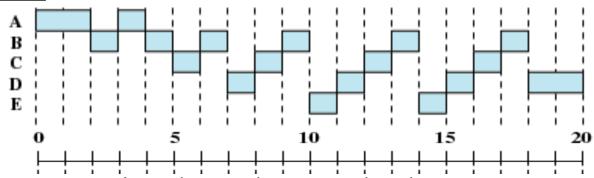

- Also called FIFO
- Performs much better for long processes
 - A short process may have to wait a very long time before it can execute
- Favors CPU-bound processes
 - I/O processes have to wait until CPU-bound process completes

Round-Robin

Table 9.4 Process Scheduling Example

Process	Arrival Time	Service Time
A	0	3
В	2	6
С	4	4
D	6	5
E	8	2

Round-Robin (RR), q = 1

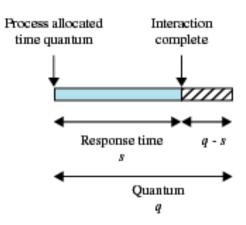

- Uses preemption based on a clock
 - quantum q
- An amount of time is determined that allows each process to use the processor for that length of time

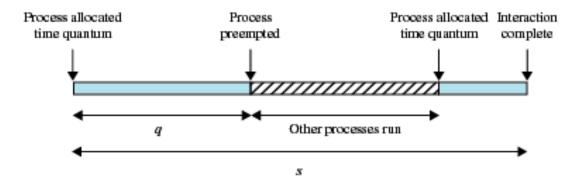

Round-Robin

- Clock interrupt is generated at periodic intervals
- When an interrupt occurs, the currently running process is placed in the read queue
 - Next ready job is selected
- Known as time slicing

(a) Time quantum greater than typical interaction

(b) Time quantum less than typical interaction

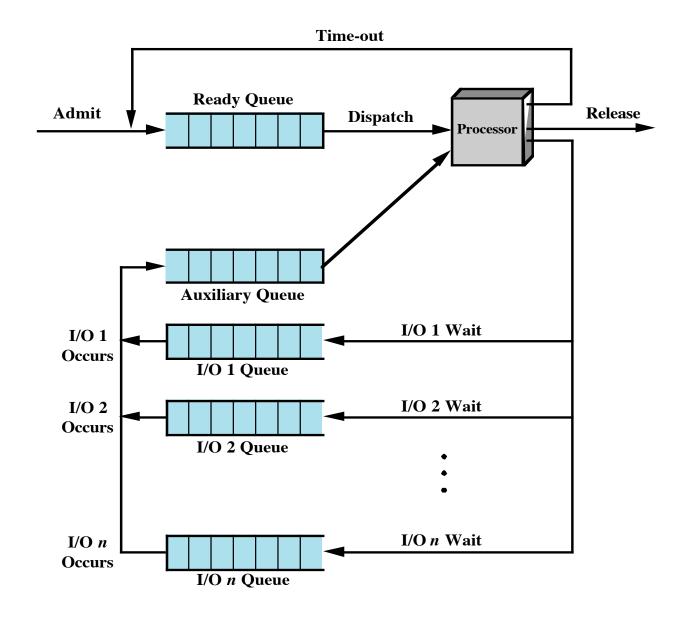

Figure 9.7 Queuing Diagram for Virtual Round-Robin Scheduler

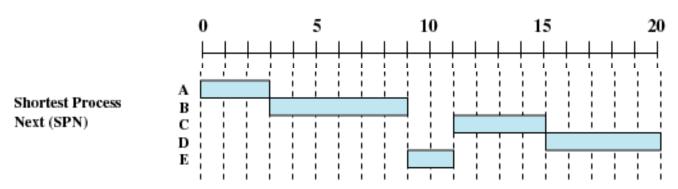

Table 9.4 Process Scheduling Example

 Nonpreemptive policy 	•	Nonpi	reemi	ptive	policy	7
--	---	-------	-------	-------	--------	---

Process	Arrival Time	Service Time
Α	0	3
В	2	6
С	4	4
D	6	5
Е	8	2

- Process with shortest expected processing time is selected next
- Short process jumps ahead of longer processes

- Need to predict (or estimate) run time
- If estimated time for process not correct, the operating system may abort it
- Possibility of starvation for longer processes

- Predictions (using simplest calculations)
 - $-T_i$ time for *i*-th instance of process
 - $-S_i$ predicted execution time for *i*-th instance
 - Simplest scenario, e.g. batch processing in burst mode

$$S_{n+1} = \frac{1}{n} \sum_{i=1}^{n} T_i$$

Avoiding recalculating entire sum

$$S_{n+1} = \frac{1}{n}T_n + \frac{n-1}{n}S_n$$

- Previous calculations assumed equal weight
 - typically give higher weight to recent instances
 - exponential averaging: α a constant weight factor (0 < α < 1)

$$S_{n+1} = \alpha T_n + (1 - \alpha) S_n$$

$$S_{n+1} = \alpha T_n + (1 - \alpha) \alpha T_{n-1} + \dots$$

$$+ (1 - \alpha)^i \alpha T_{n-i} + \dots + (1 - \alpha)^n S_1$$
