A Brief Introduction to Qt

Bruce Bolden
March 25, 2009
What is Qt\textsuperscript{1}? 

A platform independent (cross-platform) graphics library for the development of applications with/without UIs (user interfaces).

Features

\begin{itemize}
  \item Intuitive C++ class library
  \item Portability across desktop and embedded operating systems
  \item \textit{Look and Feel} of the native OS
  \item Integrated development tools with cross-platform IDE
  \item High runtime performance and small footprint on embedded systems
\end{itemize}

\textbf{Note:} Qt is pronounced \textit{cute} by Europeans.

KDE details: [http://www.kde.org/](http://www.kde.org/)
Why Qt?

• Not Java
• Platform independent (cross-platform)
• Large C++-based library
• The choice for KDE development
• Easy transition to OpenGL
Qt History

- Trolltech was founded in 1994
- Nokia acquired Trolltech ASA, in June 2008
- Active development!
  - 4.5 released March 3, 2009
  - 4.2 released August 24, 2006

This is Qt 4.5: http://www.youtube.com/watch?v=8xRfNsY53GY
Qt History—Details

Nokia acquired Trolltech ASA, in June 2008, to enable the acceleration of their cross-platform software strategy for mobile devices and desktop applications, and to develop its Internet services business. On September 29, 2008 Nokia renamed Trolltech to Qt Software.\textsuperscript{2}

Trolltech was founded in 1994. The core team of designers at Trolltech started developing Qt in 1992, and the first commercial version of Qt was released in 1995. Since then, Trolltech has experienced rapid growth, and Qt is currently used in thousands of successful commercial software development projects worldwide. At Trolltech, we continuously work to improve and expand Qt to ensure that it always represents the state of the art in usability, look and feel, performance, and stability.\textsuperscript{3}

Language Support for Qt

- Python
- Ada
- Pascal
- Perl
- PHP
- Ruby
- Java (Qt Jambi)

Note: Qt Jambi — a port of Qt to the Java programming language — has been discontinued in order to focus resources on the Qt cross platform application and UI framework. Qt Jambi will be maintained for one year after the March 2009 release of Qt Jambi 4.5.0.01, and will be made available upon release under the LGPL license.\(^5\)

Building a Qt project

The following steps can be used to build a Qt application from the command line:

- Generate a Qt project file: `qmake -project`
  Looks at all the files *and* subdirectories to generate a project file that is used to generate a makefile for the project. The name of the project file is the directory name.
  
  **Note:** Hiding files (backups) in subdirectories doesn’t seem to work, since `qmake` finds the files and adds them to the make file. Changing the name or compressing the files may hide them.

- Generate a makefile: `qmake proj.pro`

- Build application (executable): `make`

- Run/execute: `open Proj.app`
  Runs the final executable. Proper bundles are created in version 4.x.
Building MinDraw

Looking at the initial contents of the MinDraw directory before creating the project file.

drawarea.cpp  drawarea.h  main.cpp
mainwindow.cpp  mainwindow.h
Project File Creation

Create the project file using the command `qmake -project`

After creating the project file, `MinDraw.pro` is generated:

```
MinDraw.pro   drawarea.h  mainwindow.cpp
drawarea.cpp  main.cpp   mainwindow.h
```

Note that the project name is the directory with the file suffix `pro`. 
Make File Creation

Create the makefile using the command `qmake MinDraw.pro`.

After creating the makefile, we see:

```
Makefile    drawarea.cpp    main.cpp   mainwindow.h
MinDraw.pro  drawarea.h    mainwindow.cpp
```
Application Creation

After running the makefile/or using QtCreator to build the application:

<table>
<thead>
<tr>
<th>Makefile</th>
<th>drawarea.o</th>
<th>mainwindow.o</th>
</tr>
</thead>
<tbody>
<tr>
<td>MinDraw.app</td>
<td>main.cpp</td>
<td>moc_drawarea.cpp</td>
</tr>
<tr>
<td>MinDraw.pro</td>
<td>main.o</td>
<td>moc_drawarea.o</td>
</tr>
<tr>
<td>drawarea.cpp</td>
<td>mainwindow.cpp</td>
<td>moc_mainwindow.cpp</td>
</tr>
<tr>
<td>drawarea.h</td>
<td>mainwindow.h</td>
<td>moc_mainwindow.o</td>
</tr>
</tbody>
</table>

**Note:** The file names starting with `moc_`. These are generated by Qt’s meta object tool `moc`, the Meta-Object Compiler.
Some Qt Internals

- QObject
- Meta-Object System
- Signals and Slots
- Q Painter
- namespace Qt
QObject

The QObject class is the base class of all Qt objects.

```cpp
#include <QObject>
```

Note that the Q_OBJECT macro is mandatory for any object that implements signals, slots or properties. You also need to run moc (the Meta Object Compiler) on the source file. The use of the Q_OBJECT macro is strongly recommend in all subclasses of QObject regardless of whether or not they actually use signals, slots and properties, since failure to do so may lead certain functions to exhibit strange behavior.

Q_OBJECT location

The Q_OBJECT macro must appear in the private section of a class definition that declares its own signals and slots or that uses other services provided by Qt’s meta-object system.
Meta-Object System

Qt’s Meta-Object System provides the signals and slots mechanism for inter-object communication, run-time type information, and the dynamic property system.

The Meta-Object System is based on three things:

1. The `QObject` class provides a base class for objects that can take advantage of the meta-object system.

2. The `Q_OBJECT` macro inside the private section of the class declaration is used to enable meta-object features, such as dynamic properties, signals, and slots.

3. The Meta-Object Compiler (`moc`) supplies each `QObject` subclass with the necessary code to implement meta-object features. The `moc` tool reads a C++ source file. If it finds one or more class declarations that contain the `Q_OBJECT` macro, it produces another C++ source file which contains the meta-object code for each of those classes. This generated source file is either `#include`d into the class’s source file or, more usually, compiled and linked with the class’s implementation.
Additional Meta-object Features

In addition to providing the *signals and slots* mechanism for communication between objects (the main reason for introducing the system), the meta-object code provides the following additional features:

- `QObject::metaObject()` returns the associated meta-object for the class.
- `QMetaObject::className()` returns the class name as a string at run-time, without requiring native run-time type information (RTTI) support through the C++ compiler.
- `QObject::inherits()` function returns whether an object is an instance of a class that inherits a specified class within the `QObject` inheritance tree.
- `QObject::tr()` and `QObject::trUtf8()` translate strings for internationalization.
- `QObject::setProperty()` and `QObject::property()` dynamically set and get properties by name.
Dynamic Casts

It is also possible to perform dynamic casts using `qobject_cast()` on `QObject` classes. The `qobject_cast()` function behaves similarly to the standard C++ `dynamic_cast()`, with the advantages that it doesn’t require RTTI support and it works across dynamic library boundaries. It attempts to cast its argument to the pointer type specified in angle-brackets, returning a non-zero pointer if the object is of the correct type (determined at run-time), or 0 if the object’s type is incompatible.
Signals and Slots

Signals and slots are used for communication between objects. The signals and slots mechanism is a central feature of Qt and probably the part that differs most from the features provided by other frameworks.

Note: Signals in Qt are not signals in Unix-like operating systems.
The QPainter Class

#include <QPainter>

The QPainter class performs low-level painting on widgets and other paint devices.

The painter provides highly optimized functions to do most of the drawing GUI programs require. QPainter can draw everything from simple lines to complex shapes like pies and chords. It can also draw aligned text and pixmaps. Normally, it draws in a “natural” coordinate system, but it can also do view and world transformation.

The typical use of a painter (object):

1. Construct a painter.
2. Set a pen, a brush etc.
3. Draw.
4. Destroy the painter.
A common use of QPainter is inside a widget’s paint event. Here’s one simple example:

```c++
void DrawArea::paintEvent(QPaintEvent * /* event */) {
    QPainter painter(this);

    painter.setPen( Qt::red );
    painter.drawLine ( 50, 50, 350, 350 );
    painter.drawLine ( 50, 350, 350, 50 );

    painter.setPen( Qt::green );
    painter.drawText( 200, 200, "The Center" );
}
```
Prototypes for drawing a line, text, and changing the pen color:

```cpp
void QPainter::drawLine( int x1, int y1, int x2, int y2 );
void QPainter::drawText( int x, int y, const QString & text );
void QPainter::setPen();
```
namespace Qt

Is defined in src/corelib/global/qnamespace.h. The file is about 1600 (1625 to be exact) lines (was about 1300 lines long (1354 to be exact) in Qt 4.3). Numerous properties are defined in it.

Colors

enum GlobalColor {
    color0,
    color1,
    black,
    white,
    darkGray,
    gray,
    lightGray,
    red,
    green,
    blue,
    cyan,
    magenta,
    yellow,
    darkRed,
    darkGreen,
    darkBlue,
    darkCyan,
    darkMagenta,
    darkYellow,
    transparent
};
Keyboard Modifiers

```cpp
enum KeyboardModifier {
    NoModifier = 0x00000000,
    ShiftModifier = 0x02000000,
    ControlModifier = 0x04000000,
    AltModifier = 0x08000000,
    MetaModifier = 0x10000000,
    KeypadModifier = 0x20000000,
    GroupSwitchModifier = 0x40000000,
    // Do not extend the mask to include 0x01000000
    KeyboardModifierMask = 0xfe000000
};
Q_DECLARE_FLAGS(KeyboardModifiers, KeyboardModifier)
```
